**Demo Setup**

1. Import file hierarchy into XML database
2. Extract metadata based on file types
3. Store BLOBs in backing store
4. Mount database as filesystem in userspace
5. Use XPath/XQuery on filesystem data
6. Use conventional OS applications

**XML Filesystem View**

Via Extractors we store queryable metadata for specific file types in XML.

**System Architecture**

General approach:
All queryable data in the filesystem shall be stored in the database. As such, querying the filesystem is querying XML.
